Introduction

- University of Birmingham - Tool for Isotope Production[1] aims to utilise the benefits of nuclear reaction codes such as **EMPIRE**[2], **TALYS**[3] and precompiled **TENDL**[5] data
- Automating execution and data processing
- Calculating production **cross-section** and production **yield**
- While leveraging the benefits of existing infrastructure this package aims to **streamline calculations**
- Output data in a clear and concise **machine and human readable format**
- Provide intuitive **data visualisations**
- Utilise nuclear decay data from **ENDF**[6] and stopping power from **SRIM**[4] by default
- Enable calculations with **complex targets including molecular or compound** and accounting for impurities in the target

Aims

- Automate reaction calculations
- Allow complex targets (molecules and compounds)
- Run a large number of reactions easily
- Clear and concise data outputs
- Intuitive data visualisations
- Run yield calculations with user data
- Easy to use interface

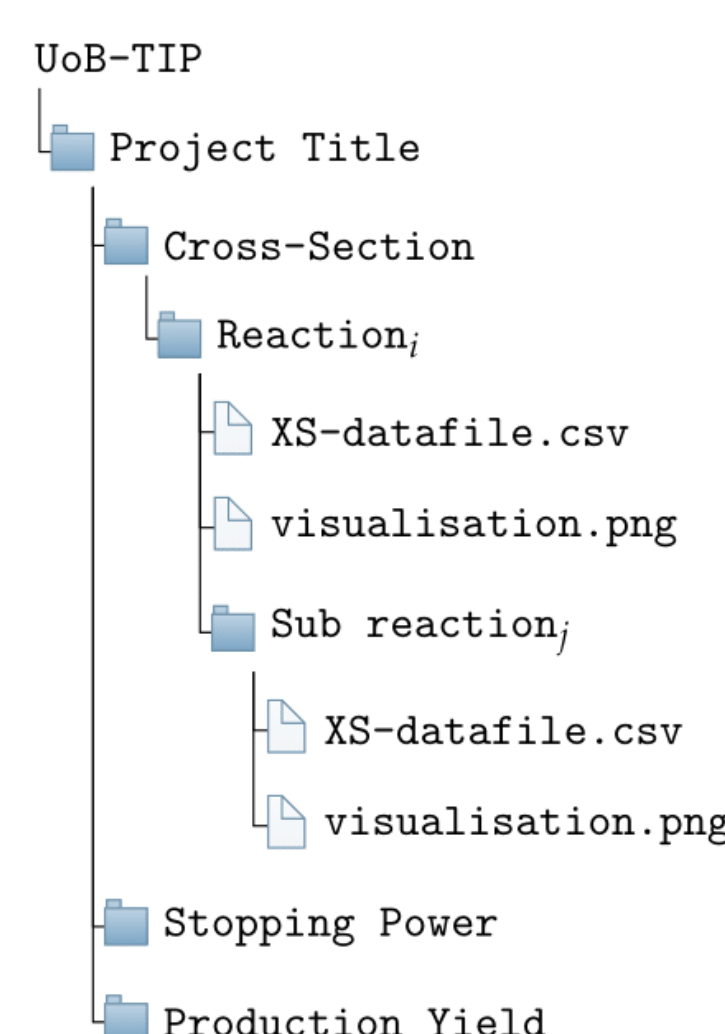

Installation and usage

UoB-TIP is available through a variety of routes

- Python** package (pip, conda)
- Docker** container
- Executable with a **GUI** interface
- Released later this year**
- For be kept up to date with release **register interest with: r.allen.4@pgr.bham.ac.uk**

UoB-TIP Data Structures

UoB-TIP outputs data in a **nested directory** for reactions and sub-reactions as shown in the figure below.

- .csv output** file containing all data
- A row for each product

- Each product contains product name, excitation energy, half-life and cross-section data

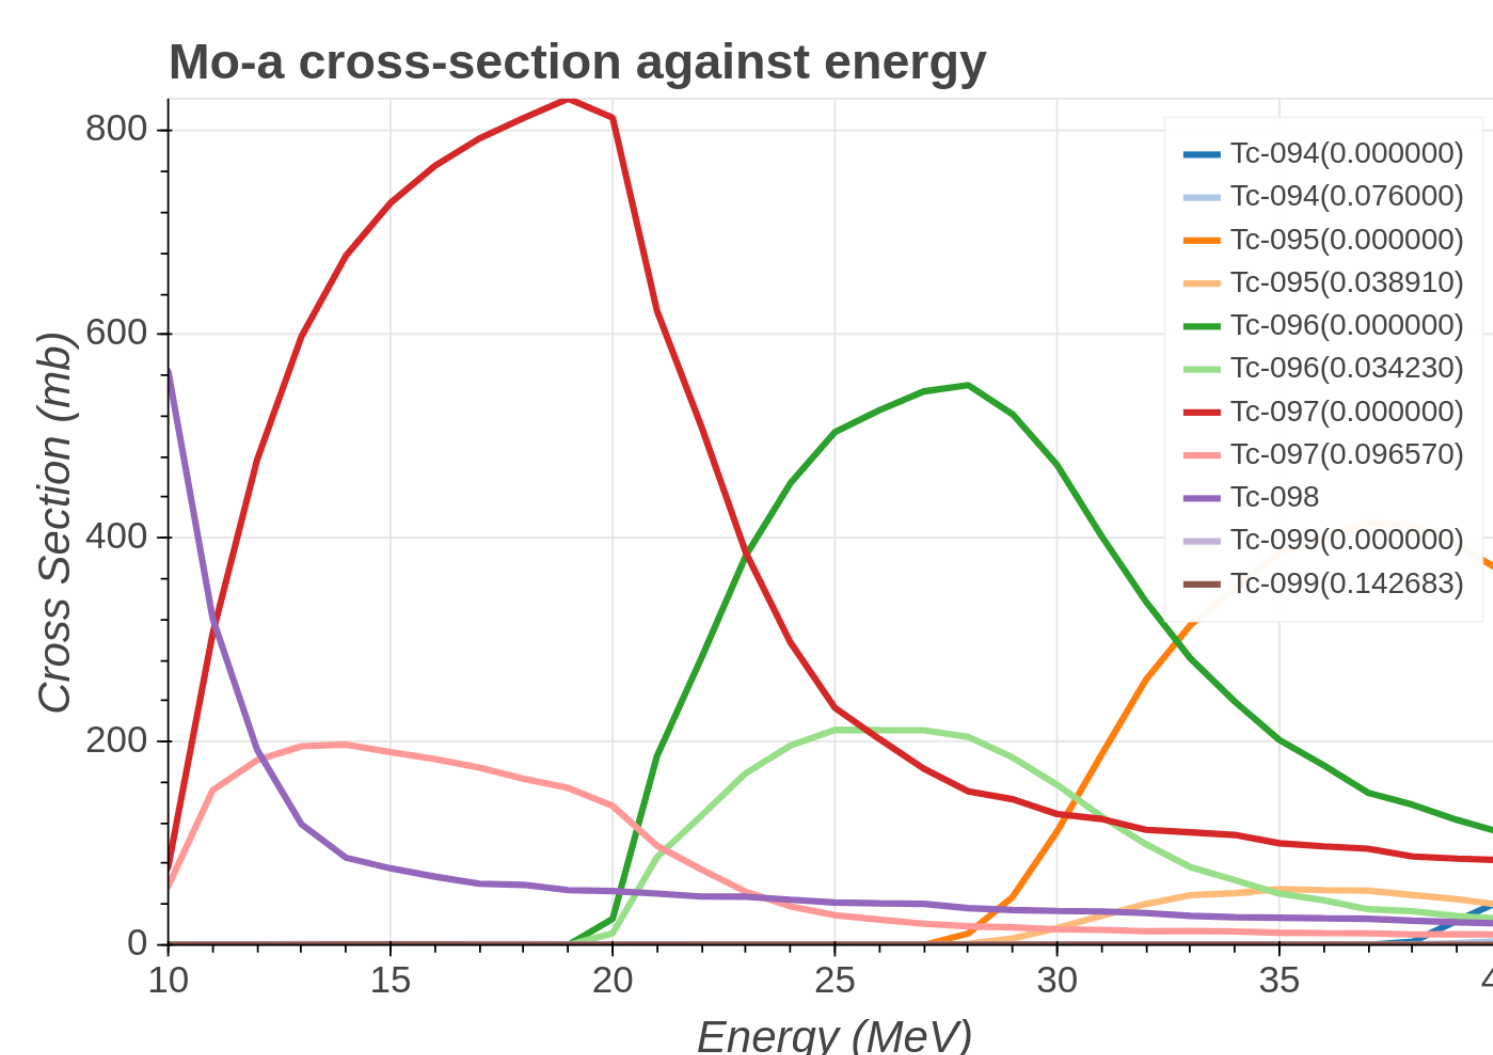

Product	Half-life	decay types	E ₁	E ₂	E ₃	E ₄	...	E _n
---------	-----------	-------------	----------------	----------------	----------------	----------------	-----	----------------

User Inputs

- Two input categories, reaction and yield inputs
- Reaction inputs** include: target, projectile, and optional nuclear model parameters
- Yield inputs** include: beam current, irradiation time, beam energy and target thickness

Cross-Section

- Calculated using TALYS or EMPIRE (user specified)
 - Large amount of **optional nuclear parameterisation**
- Alternatively cross-section data can be extracted from TENDL data files

Reaction Rate

- Reaction rate is the number of **reactions per second** for a given reaction channel
- Determined by cross-section, target thickness, beam current and irradiation time

$$R_{A \rightarrow B} = \frac{I_{beam}}{z_p q_e} \frac{1}{V_{tar}} \int_{E_f}^{E_i} \left(\frac{dE}{dx} \right)^{-1} \sigma_i(E) dE \quad (1)$$

Stopping Power

- Contains **pre-calculated stopping power** from SRIM
 - For ¹H, ²H, ³He and ⁴He projectiles
 - For all elements Z=1 to Z=115
 - For energies 0→100MeV
- Users **may define their own stopping power** using a .csv (for complex targets and higher energies)

Inventory Calculations

- Inventory calculations cover the quantity of products (in terms of **mass and activity**) with respect to time during irradiation and subsequent cooling.
- For the simple case where $A \rightarrow B_1 \rightarrow C_1$. A is the target isotope, which produces B upon irradiation, B₁ is unstable and decays into B₂
- The number of particles of B₁ with respect to time during irradiation is:

$$N_{B_1}(t) = \frac{R_{A \rightarrow B_1}}{\lambda_{B_1}} (1 - e^{-\lambda_{B_1} t_{irrad}}) e^{-\lambda_{B_1} t_{cool}} \quad (2)$$

- The scenario becomes more complex with some products **produced both directly by the beam** and through the **decay of other isotopes**, as well as the decay of other products
- Several reasonable assumptions are made:
 - Only the target isotopes are present at t=0
 - The beam only interacts with target isotopes

- A product, B₁ which is produced both through the beam interacting with the target, A, as well as the decay of isotopes, B₂.

The number of B₂ with respect to time is given as:

$$N_{B_2}(t) = N_A(0) \frac{R_{A \rightarrow B_2}}{\lambda_{B_2} - R_A} \left[e^{-R_A t} - e^{-\lambda_{B_2} t} \right] + N_A(0) \frac{R_{A \rightarrow B_1} \lambda_{B_1 \rightarrow i}}{\lambda_{B_1} - R_A} \left[\frac{e^{-R_A t} - e^{-\lambda_{B_2} t}}{\lambda_i - R_A} - \frac{e^{-\lambda_{B_1} t} - e^{-\lambda_{B_2} t}}{\lambda_{B_2} - \lambda_{B_1}} \right] \quad (3)$$

- Activity** may be calculated from the number of radioactive nuclei:

$$A_i = N_i \lambda_i \quad (4)$$

- A .csv file is produced containing the activity or number of **quantity of products against irradiation and cooling time**
- This may also be plotted, showing any number of products, as below for ⁹⁹Mo(p,n)^{99m}Tc

Decay Energies

- Gamma and alpha spectra may be predicted** at any time, t, during or following irradiation using activities calculated from ENDF decay data
- This is **shown below for ^{nat}Mo-p** predicted overlaid with a spectrum taken using a HPGe detector

- Future implementations** include Gaussian energy broadening, background and efficiency
- These data may be used as **initial paramaterisation for automatic peak fitting**
